1.	<i>Program to display menus of ATM using switch statement.</i>
2.	<i>Program to find vowels using switch statement.</i>

# 1. Using switch statement program to display menus of ATM.

Page | 2

## Abstract :

*The ATM Program in C is written in C programming language which provides an ease to read and comprehend the instructions used. This program for using ATM machine is built on the concept of handling an account individually.*

*From this ATM program in C, we can even use the mini-program for checking the total balance, depositing the amount, and withdrawing the amount from the account definitely since it is not time overwhelming.*

## *What is switch statement....??????*

*A **switch** statement allows a variable to be tested for equality against a list of values. Each value is called a case, and the variable being switched on is checked for each **switch case**.*

The following rules apply to a **switch** statement –

- *The **expression** used in a **switch** statement must have an integral or enumerated type, or be of a class type in which the class has a single conversion function to an integral or enumerated type.*
- *You can have any number of case statements within a switch. Each case is followed by the value to be compared to and a colon.*
- *The **constant-expression** for a case must be the same data type as the variable in the switch, and it must be a constant or a literal.*
- *When the variable being switched on is equal to a case, the statements following that case will execute until a **break** statement is reached.*
- *When a **break** statement is reached, the switch terminates, and the flow of control jumps to the next line following the switch statement.*
- *Not every case needs to contain a **break**. If no **break** appears, the flow of control will fall through to subsequent cases until a break is reached.*
- *A **switch** statement can have an optional **default** case, which must appear at the end of the switch. The default case can be used for performing a task when none of the cases is true. No **break** is needed in the default case.*

## Syntax :

```
switch(expression)
{
case value1:  statement_1; break;

case value2:  statement_2; break;

.....

.....

case value_n:  statement_n; break;

default:  default statement;

}
```

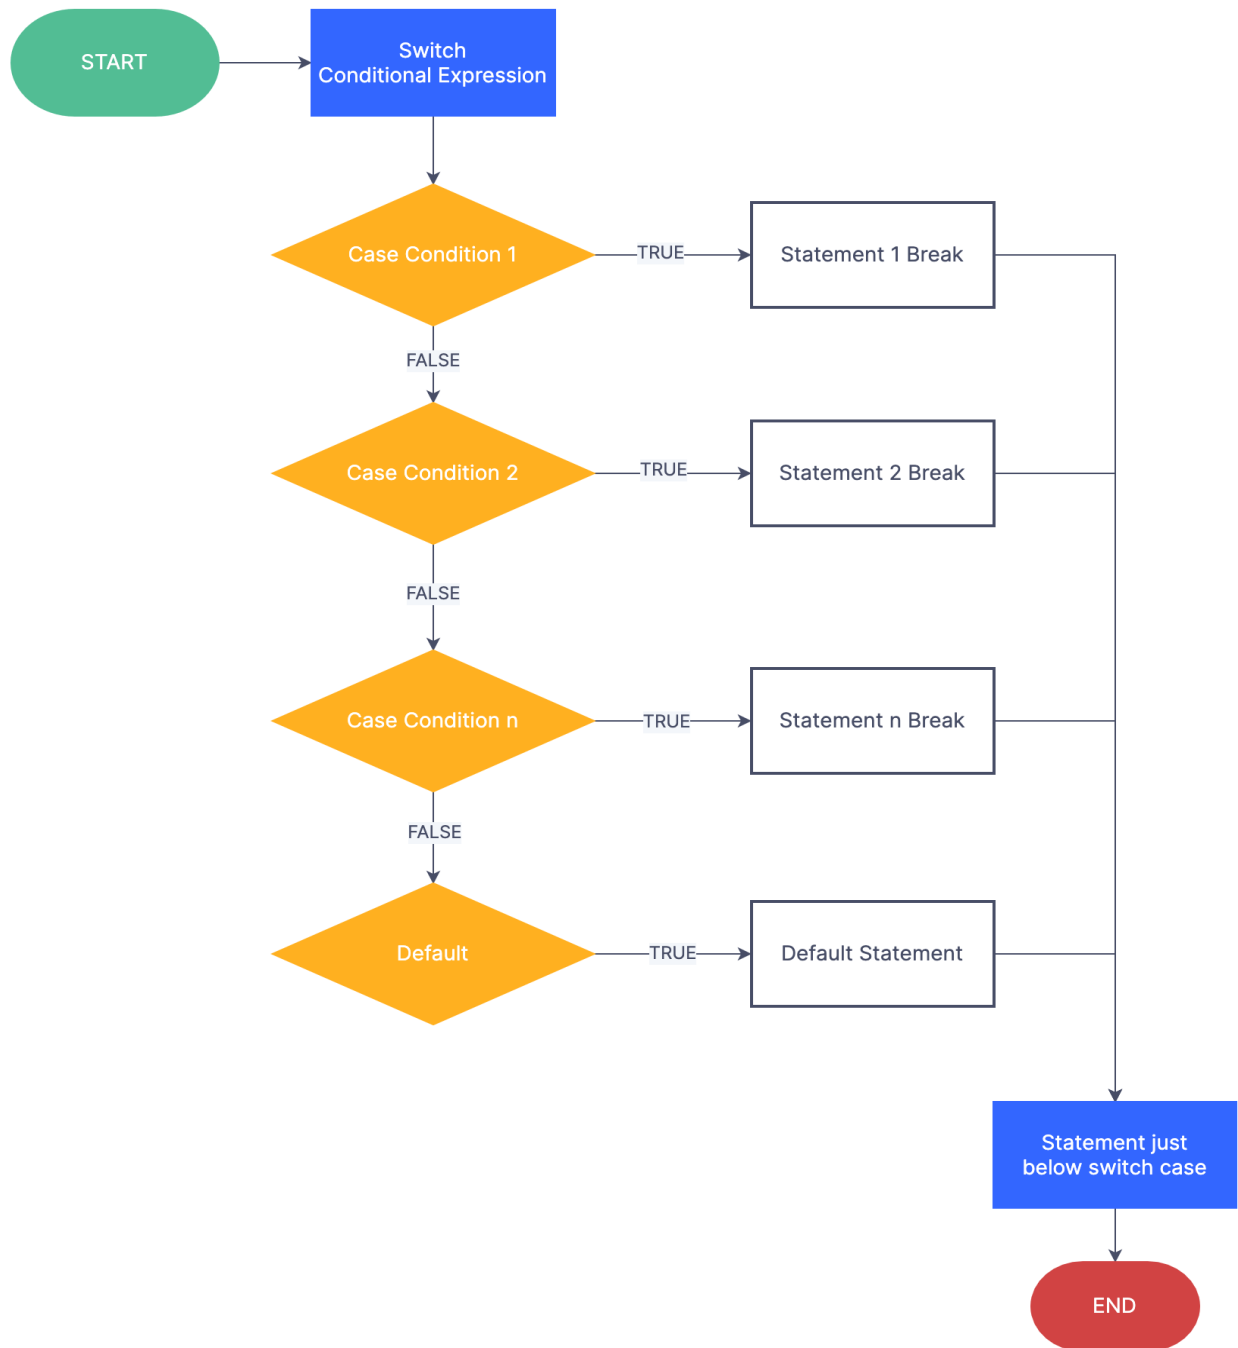

### ***Some important keywords:***

***1) Break:*** This keyword is used to stop the execution inside a switch block. It helps to terminate the switch block and break out of it.

***2) Default:*** This keyword is used to specify the set of statements to execute if there is no case match.

***Note:*** Sometimes when ***default*** is not placed at the end of switch case program, we should use ***break statement*** with the default case.

# Switch Case Flowchart

*A **switch case flowchart** describes program execution via a graphical representation for simplifying computer programming languages. By displaying a consistent logical sequence between code blocks, the chart brings an easy way to manage multiple cases. This is one of the use cases of flowchart in programming.*

# Algorithm

*Step1: start*

*Step2: Read  $x, y$ ;*

*Step3: Calculate the answer depending on the operator and print it*

*Enter the  $c$  for credit,  $b$  for balance,  $d$  for debit*

*Enter the credit amount*

*If  $x = x + y$*

*Print answer = net amount and go to step4*

*Enter debit amount*

*If  $x \geq y$  print ans = net amount and go to step4*

*If  $x = x - y$*

*Print answer = net amount*

*Else*

*Print ans = insufficient amount go to step4*

*Else print choose correct option for operation*

*Goto try again*

*Step4: stop*

## Program:

```
#include<stdio.h>
```

Page | 6

```
int main()
```

```
{
```

```
Float x,y;
```

```
Char ch;
```

```
Printf("Enter \n c for credit \n d for debit \n b for  
balance \n");
```

```
Scanf("\n%c",&ch);
```

```
Switch(ch)
```

```
{
```

```
Case 'c':
```

```
Printf("Enter the credit amount: \n");
```

```
Scanf("\ %f",&y);
```

```
x=x+y
```

```
printf("net amount=%f",x);
```

```
break;
```

```
case 'd':
```

```
printf("Enter debit amount: \n");
```

```
scanf("%f",&y);
```

```
if(x>=y)
```

```
{
```

Page | 7

```
x=x-y
```

```
printf("net amount=%f",x);
```

```
}
```

```
else
```

```
{
```

```
Printf("insufficient amount=%f",x);
```

```
}
```

```
break;
```

```
case 'b':
```

```
printf("amount in account:%f",x);
```

```
break;
```

```
default:
```

```
printf("choose correct option for operation");
```

```
goto tryagain;
```

```
}
```

```
Return(0);
```

```
}
```

*Output:*

*b Enter initial amount*

Page | 8 *5000*

*Enter*

*c for credit*

*d for debit*

*b for balance*

*c*

*Enter credit amount*

*2000*

*New amount=7000.00*

*Enter initial amount*

*5000*

*Enter*

*c for credit*

*d for debit*

*b for balance*

*d*

*Enter debit amount*

*3000*

*New amount=2000.00*

*Enter initial amount*

*6000*

*Enter*

*c for credit*

*d for debit*

*b for balance*

*d*

*Enter debit amount*

*8000*

*Insufficient balance in your account*

*Enter initial amount*

*4500*

*Enter*

*c for credit*

*d for debit*

*b for balance*

*Amount in your account=4500.*

## 2.Program to find vowels using switch statement

Page | 10

### Abstract:

To check whether the input alphabet is a vowel or consonant in C programming, you have to ask from user to enter a character and check if the given character is equal to a, A, e, E, i, I, o, O, u, U or not. If it is equal to any one of these 10, then it is a vowel, otherwise it is a consonant. Let's have a look at the program:

### Algorithm:

*Step 1.: Start*

*Step 2.: Declare character type variable ch.*

*Step 3.: Read ch from user.*

*Step 4.: Checking vowels.*

*If (ch==a*

*Ch==e*

*Ch==i*

*Ch==o*

*Ch==u)*

*Print"vowel"*

*Else*

*Print"consonant"*

*Step 5.: stop*

## Program:

```
#include<stdio.h>
```

```
Void main()
```

```
{
```

```
char alphabet;
```

```
printf("Enter an alphabet\n");
```

```
scanf("%c",&alphabet);
```

```
switch(alphabet)
```

```
{
```

```
Case 'a':
```

```
Printf("It is vowel");
```

```
break;
```

```
Case 'e':
```

```
Printf("It is vowel");
```

```
break;
```

```
Case 'i':
```

```
Printf("It is vowel");  
break;
```

Page | 12

*Case 'o':*

```
Printf("It is vowel");  
break;
```

*Case 'u':*

```
Printf("It is vowel");  
break;
```

*default:*

```
printf("It is a consonant");  
}  
getch();  
}
```

# *Output:*

Enter an alphabet

a

It is vowel

Enter an alphabet

e

It is vowel

Enter an alphabet

i

It is vowel

Enter an alphabet

o

It is vowel

Enter an alphabet

u

It is vowel

Enter an alphabet

b

It is consonant

## Conclusion:

*A switch statement allows a variable to be tested for equality against a list of values. Each value is called a case, and the variable being switched on is checked for each switch case. C is most useful for embedded systems, or applications that require the ability to be light-weight and have precise control over system resources.*
